VS Code Setup: Centralized Prompts & Knowledge base Integration

Centralize Your Prompts and Knowledge Base with VS Code

Prerequisites: Ensure that Github Copilot is functioning properly and free of any errors.

1. Begin by cloning the following two repositories that contain your prompts and knowledge base:
   a. AI.Prompts - Repos
   b. AI.KnowledgeBaseAndStandards - Repos
2. Once you have cloned both repositories, open Visual Studio Code and follow these steps:
   a. Access the VS Code Settings by pressing **Ctrl + ,**
   b. In the search bar, type `chat.promptfile`.
   c. Click "Add Item" to include the location of the cloned prompt folder, then set the path and value to true.

d. 
e. After configuring the prompt, search for `chat.instruction`.

f. Click "Add Item" to include the location of the cloned instruction folder, then set the path and value to:

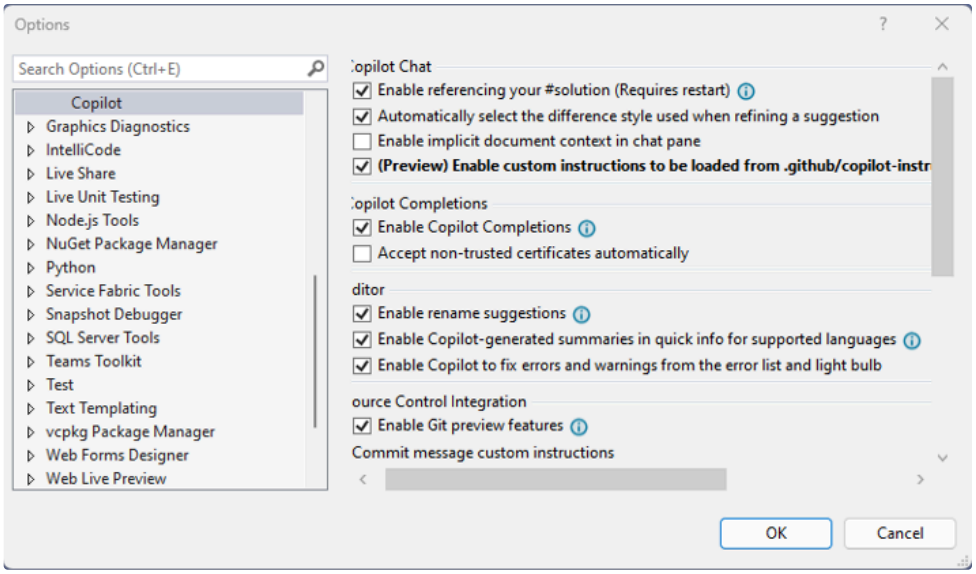
g. 
3. After completing both settings, open a repository in Visual Studio Code to test your configurations.
4. Launch GitHub Copilot and initiate the prompt by entering /{prompt name}. For example, use /story.
   a. 
   b.
      i. When you initiate a prompt and encounter the error described below, please follow these steps:
      ii. 
      iii. Click on the tools settings icon and select the tools you wish to use. Please keep in mind that the maximum number of tools allowed is 128.

c.

d. 
5. For copilot to work better with your repository, add `.github/copilot-instructions.md`.
   a. GitHub Copilot can provide chat responses that are tailored to the way your team works, the tools you use, or the specifics of your project, if you provide it with enough context to do so. Instead of repeatedly adding this contextual detail to your chat questions, you can create a file that automatically adds this information for you.
   b. Its main purpose is to provide Copilot with customized instructions on how it should behave in the context of your codebase. You can specify things like:
      - Naming conventions
      - Folder structure
      - Technologies in use
      - Team best practices
      - Any relevant information to improve Copilot's suggestions
   c. You can create a folder named "`instructions`" within the `.github` directory. This folder can be used to include project-specific context or a knowledge base related to the application, as well as the intent and functionality of the module.
   d. This file serves as a repository for your project-specific knowledge base, providing the copilot with essential context regarding the nature of your project or module and the problems it aims to address.

e. Project standards applicable to all repositories are established in the AI.KnowledgebaseAndStandard repository. For project-specific configurations, you can make adjustments in the Adding custom instructions for GitHub Copilot - GitHub Docs file and within the instructions folder.

f. 
6. In Visual Studio, navigate to **Tools** → **Options**.

a. In the search bar, type "Copilot" and enable the setting for “Enable custom instruction to be loaded from...”.


b.
